- A. On one of the web servers
- B. On the back end
- C. Through a security group
- D. On the front end

**Answer: D**

Explanation:

You can place an elastic network interface on each of your web servers that connects to a mid-tier network where an application server resides. The application server can also be dual-homed to a back-end network (subnet) where the database server resides. If it is set up like this, instead of routing network packets through the dual-homed instances, each dual-homed instance receives and processes requests on the front end and initiates a connection to the back end before finally sending requests to the servers on the back-end

network.
